As the sample size goes up, impact of this prior belief is minimized. A common method in Bayesian inference is to use the uninformed prior. This means that we are assuming equal likelihood for all the events. For a binomial distribution we can use beta distribution to model our prior belief.

Calculate the Bayesian average power for each sample size combination, which is obtained as $1 - \beta$. 3. Fit a curve or surface through the β Bayesian power values and find an adequate sample size combination for the desired power. In the case of one NGS test, steps 2(i)–2(iii) need to be altered.

3 Description of sample size determination algorithm. The sample size determination method uses a Monte Carlo simulation approach to generate data randomly selected from the design priors for a fixed n and to analyze the data using the proposed model. This is repeated for multiple sample sizes and in most cases the smallest sample size for which some optimality criteria has been achieved is selected as the preferred sample size.

Bayesian sample size determination for cost-effectiveness ...

Abstract. Several criteria for Bayesian sample size determination based on lengths and coverages of posterior credible intervals have recently appeared in the literature. Some but not all of these have been applied to estimating sample sizes for normal distributions. In this paper, these criteria are applied to find sample sizes for single normal means and differences between two normal means, both when the variances are known and when they are unknown.

Here, we propose three new sample size determination methods that take into account both worthwhileness and unpromisingness by means of the "Bayesian index" proposed by Kawasaki and Miyaoka [18] for two-arm clinical trials with a binary endpoint.

A method is proposed to determine sample size for inspection of general corrosion. The proposed method is based on Bayesian updating approach. An analytical formula to estimate the sample size is introduced. The effect of prior knowledge on the sample size determination is discussed.

as the coverage probability or length of a defined density region. Our Bayesian methodology can be applied to circumstances where the common variance in the new experiment is known or unknown. Exact solutions are available based on most of the criteria considered for Bayesian sample size determination, while a search procedure

Bayesian Methods Used in Sample Size Determination Let θ be an unknown parameter vector that is derived to be estimated and Θ be the parameter space for θ . Suppose it is desired to determine the sample size n where a random sample $X = (X_1, X_2, \dots, X_n)$ is to be used for the estimation of θ . According

Bayesian Sample Size Determination In contrast to the ALCK, the ACCkxes the length of the HPDinterval to be land determines the smallest nthat provides a k-th average posterior coverage of at least 1. When k= 1, the ACCk reduces to the ACC. 2.2. For details on this topic, see, among others, Weiss (1997), Wang and Gelfand (2002) and De Santis (2004).

In the inferential Bayesian methods of sample size determination, we are solely concerned with the inference about the parameter (s) of interest. The fully Bayesian or decision theoretic approach treats the problem as a decision problem and employs a loss or utility function.

In addition, a full Bayesian approach using decision theory to determine optimal sample size is given for INB. The full Bayesian approach, based on the value of information, is proposed in reaction to concerns that traditional methods rely on arbitrarily chosen error probabilities and an ill-defined notion of the smallest clinically important difference.

Several different methods have been proposed, including hybrid frequentist-Bayesian, 9 –12 fully decision theoretic 13 –16 and interval-length based approaches. 17 –19 Whitehead et al. 8 have advocated a variant of the latter which is comparable in simplicity to the frequentist sample size calculation (equation (1)) and includes an analogy to frequentist type I and II errors.

The purpose of the ?rst part of the research is to obtain Bayesian sample size determination (SSD) using loss or utility function with a linear cost function. A number of researchers have studied the Bayesian SSD problem. One group has considered utility (loss) functions and cost functions in the SSD problem and others not.

We investigate the binomial sample size problem using generalized versions of the Average Length and Average Coverage Criteria, the Median Length and Median Coverage Criteria, as well as the Worst Outcome Criterion and its modified version. We compare sample sizes derived from highest posterior density and equal-tailed credible intervals.
